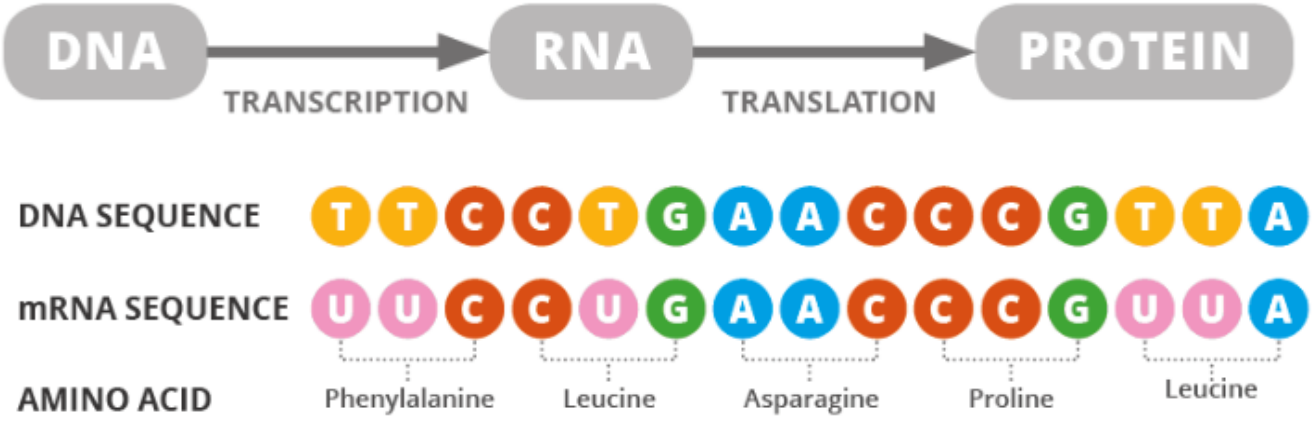
Proteins

- A chain of amino acids makes a protein



- The long chain folds around in on itself to create a shape
- This shape governs its function
- A group of proteins is called a proteome
- "Proteomics": mass spectrometric analysis of proteins

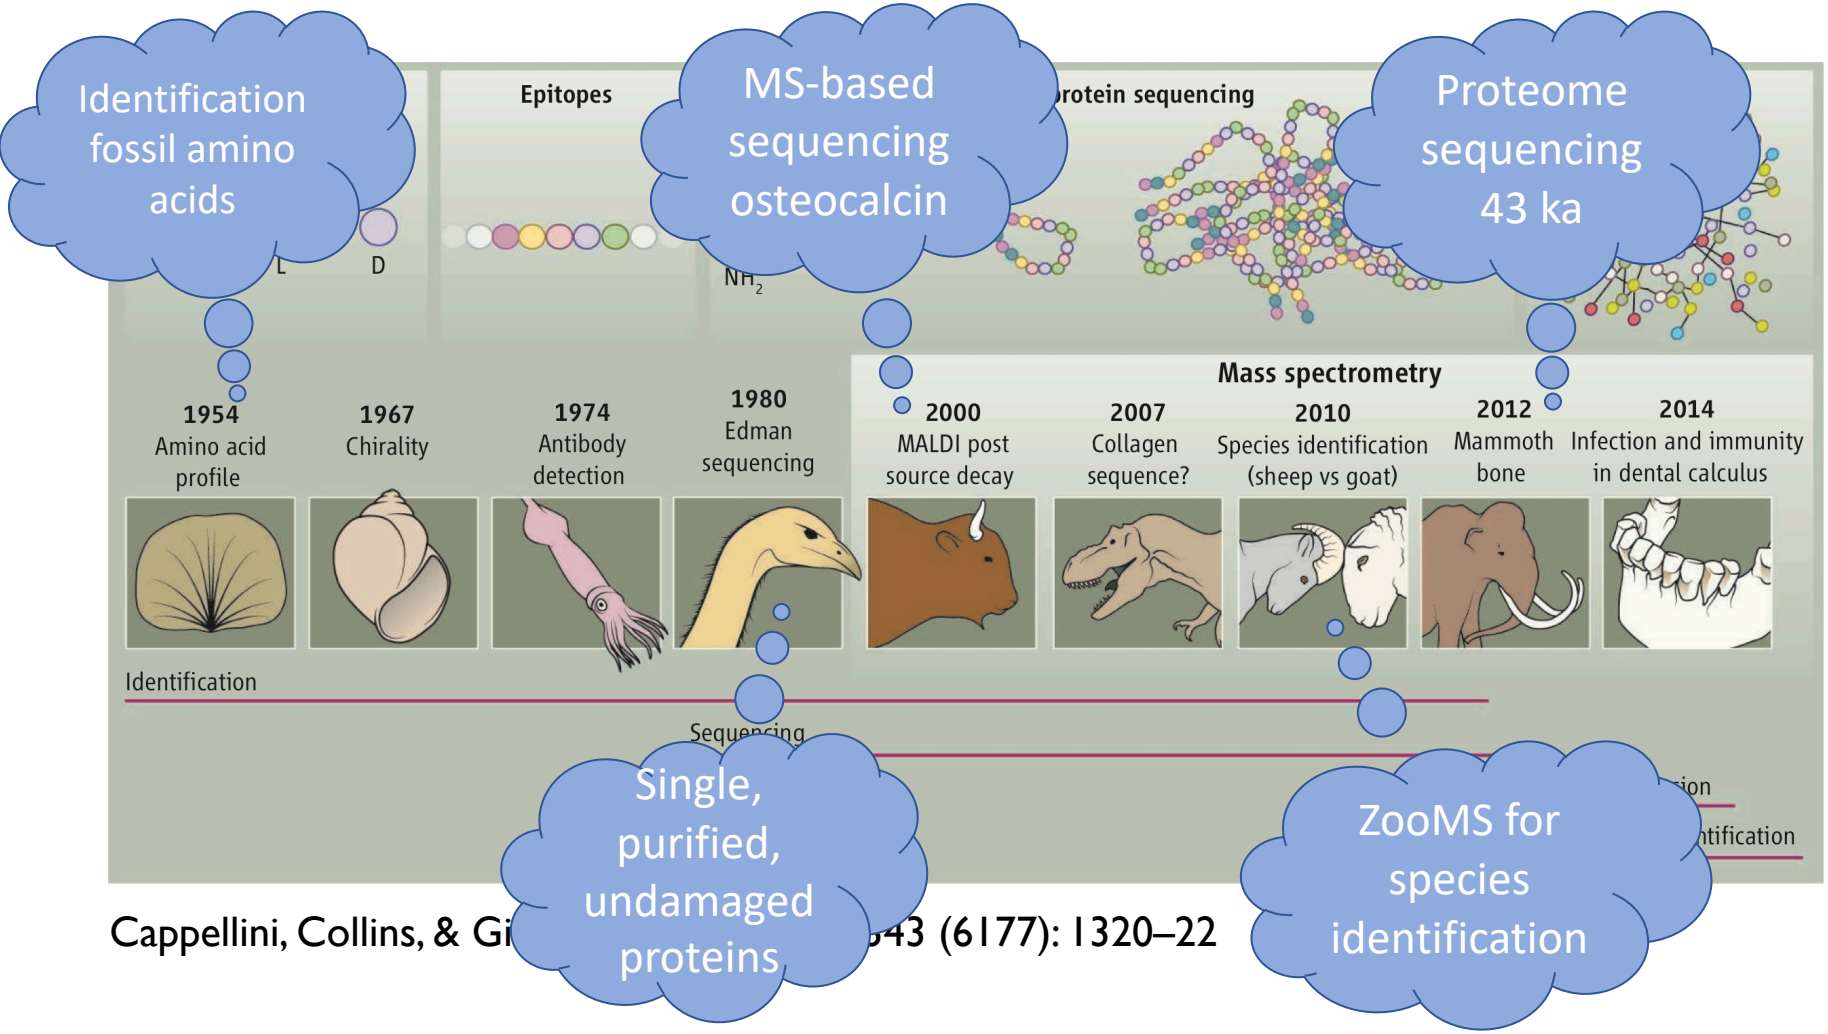
Palaeoproteomics : Ancient Protein Analysis

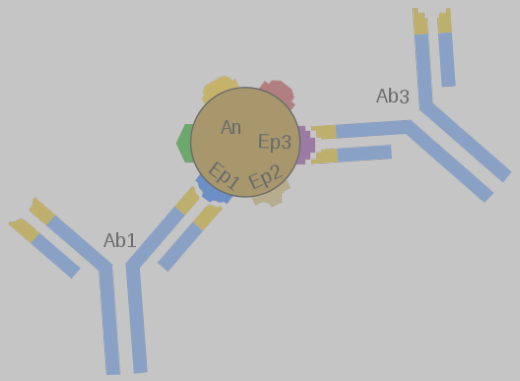
The study of ancient proteins (identification, quantification, modification)



Cappellini, Collins, & Gi 43 (6177): 1320–22

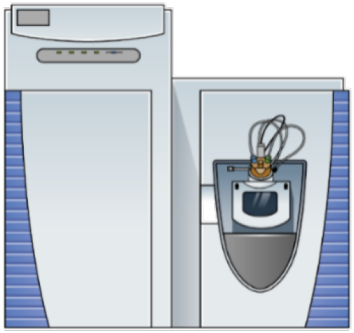
Protein Analysis Techniques & Technology

Antibody methods



- Based on epitope binding
- Targeting single proteins of interest
- Detects presence or absence
- Cheap

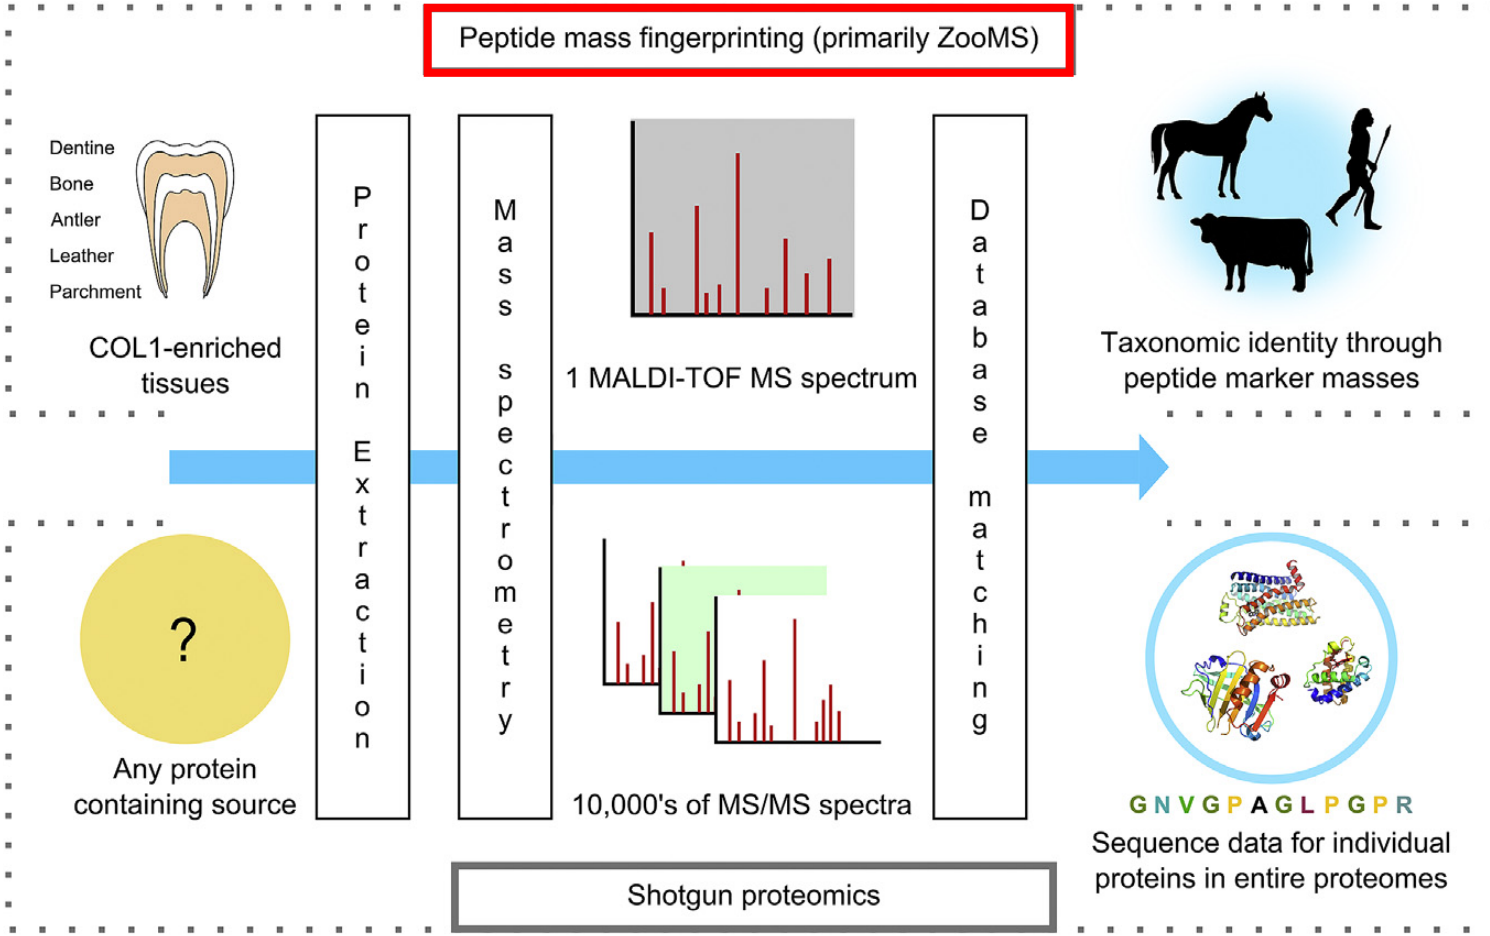
Mass Spectrometry



- Based on the detection of distinctive masses
- Generates peptide sequence information
- Expensive

Palaeoproteomics

Two approaches: **1. PMF**: MALDI TOF-MS **2. Shotgun proteomics**: LC- MS/MS



Welker et al. 2018

1. PMF => MALDI-TOF MS: total mass of individual peptides within an extract
2. Shotgun => LC-MS/MS: mass and exact amino acid sequence of the preserved peptides

Rely on presence and detection of SAPs (single amino acid polymorphisms) derived from nucleotide substitutions (SNPs, single nucleotide polymorphisms) at the genome level

Abstract

We present a novel method for the isolation and analysis of the bone collagen (I) α2 chain carboxytelopeptide as a species biomarker. Conventional methods for the analysis and sequencing of mixtures of proteins and peptides commonly involve using the protease trypsin to cleave proteins present in the sample. However, in the study of collagen, these methods result in very complex mixtures of peptides that are difficult to analyze and the acquired results are not reproducible. Here we use bacterial collagenase (from *Clostridium histolyticum*) for its ability to cleave the highly unusual Gly-Xaa-Yaa repeating sequence of collagen, where Xaa usually is Pro and Yaa often is Hyp. Followed by a simple isolation step using a reverse phase solid phase extraction cartridge, the α2 (I) chain carboxytelopeptide can be readily analyzed by matrix-assisted laser desorption/ionization–mass spectrometry (MALDI–MS) and the results can be used to distinguish between different species of origin.

Received 2 August 2009; Revised 23 September 2009; Accepted 29 September 2009

Species identification of fragmentary bone, such as in rendered meat and bone meal or from archaeological sites, is often difficult in the absence of clear morphological markers. Here we present a robust method of analysing genus-specific collagen peptides by mass spectrometry simply by using solid-phase extraction (a C18 ZipTip®) for peptide purification, rather than liquid chromatography/mass spectrometry (LC/MS). Analysis of the collagen from 32 different mammal species identified a total of 92 peptide markers that could be used for species identification, for example, in processed food and animal feed. A set of ancient (>100 ka@10°C) bone samples was also analysed to show that the proposed method has applications to archaeological bone identification. Copyright © 2009 John Wiley & Sons, Ltd.

Conclusions

- Ancient proteomics is a fast developing field
- ZooMS is a rapid and reliable method of identifying fragmented bone to taxon;
- FINDER aims to reveal the spatial distribution of archaic hominins in the late Pleistocene, particularly in eastern Eurasia; we have identified 8 hominin bone fragments from Denisova using this method, based on screening of >9000 samples;
- Many archaeological assemblages waiting to be analysed.
